

# Recitation 21: Monads

Design pattern for function + something more,  
"computation"

## Examples

- functions that sometimes fail

$2 / 0 \rightarrow \text{exception}$

Alternatively: (no exception)  $2 / 0 = \text{None}$

$\text{let div } a \ b = \text{ if } b = 0 \text{ then None else Some } (a/b)$

- functions that produce log strings when called

$\text{let log} = \text{ref } ""$

$\text{let inc } x = \text{log} := !\text{log} \wedge \text{"inc called"}$

Alternatively (no globals)

$\text{let inc } x = (x+1, \text{"inc called"})$

- functions that "run later" and whose results are used only after they run

$\text{let line} = \text{Lwt\_io. read\_line stdin}$

## "Upgraded" output types

$\text{int} \rightarrow \text{int } \underline{\text{option}}$

$\text{int} \rightarrow \text{int } * \underline{\text{string}}$

$\text{Lwt\_io. input\_channel} \rightarrow \text{string } \underline{\text{Lwt.t}}$

In general:

"vanilla":  $'a \rightarrow 'b$

"upgraded":  $'a \rightarrow 'b \ t$

Problem: how to compose?

$\lambda a. \dots \lambda x. \lambda y. \lambda z. \dots$

(div 4 2) 1 / div 4

What does div do with None input?

inc x 1 > inc doesn't typecheck

What does first inc do w/ log of second inc?

→ What we want: propagate None

→ what we want: concatenate logs

Don't want div  
inc to handle this - tons of boilerplate

Have to do this in dec, mult, etc.

Instead, define new pipeline operator >>=  
pronounced "bind".

Then: div 4 2 >>= div 4

inc x >>= inc

Recall our upgraded functions look like  $a \rightarrow 'b \ t$

so  $(\gg=) : 'a \ t \rightarrow ('a \rightarrow 'b \ t) \rightarrow 'b \ t$

Think "unbox & apply":

How we define  $\gg=$  depends on what we want.

For option:

let  $(\gg=) \ m \ f = \text{match } m \text{ with}$

! None  $\rightarrow$  None (\* propagate None \*)

! Some  $x \rightarrow f \ x$

For logging:

let  $(\gg=) \ (\text{input}, \text{prev-log}) \ f$

let  $(\text{output}, \text{log-entry}) = f \ \text{input}$  in

(output, prev\_log 1 log\_entry)

For promises, complicated, but basically

let ( $\gg=$ ) m f =

<Wait for promise m to run>

match m with

Resolved input  $\rightarrow$  f input

$\gg=$  basically tells how to compose

Can use it to define composition of upgraded funcs.

Recall ordinary composition:

let Compose f g = fun x  $\rightarrow$  f x |> g

let ( $\gg$ ) = compose

For upgraded funcs:

let compose' f g = fun x  $\rightarrow$  f x  $\gg=$  g

let ( $\gg=$ ) = compose'

same!

What is a monad?

Basically, upgraded type plus def of  $\gg=$

Definition has to "make sense" (monad laws)

Technically:

module type Monad = sig

type 'a t

val ( $\gg=$ ) : 'a t  $\rightarrow$  ('a  $\rightarrow$  'b t)  $\rightarrow$  'b t

val return: 'a  $\rightarrow$  'a t (\*wraps a value\*)

end

## Examples

- option:  $\text{return } x = \text{Some } x$
- logging:  $\text{return } x = (x, "")$
- promises:  $\text{return } x = \text{Resolved } x$

Most trivial way to "upgrade" a value.

## Monad laws

- Any data structure has expected behavior ("laws")
- $\text{pop}(\text{push } x \text{ } s) = x$
- option monad:  $\text{None} \gg f = \text{None}$

That was specific to option monad, but turns out there are some laws that all monads satisfy.

- function composition is associative

$$f \gg (g \gg h) \cong (f \gg g) \gg h$$

For upgraded functions

means "behaves the same as"

$$f \ggg (g \ggg h) \cong (f \ggg g) \ggg h$$

- identity

$$f \gg \text{id} \cong f \cong \text{id} \gg f$$

For upgraded functions

$$f \ggg \text{return} \cong f \cong \text{return} \ggg f$$

- In practice: means client of monad

- doesn't need to worry about order of composition

- can think of  $\text{return}$  as a trivial "no-op"

- Can write in terms of  $\text{bind}$

$$(m \gg= f) \gg= g \cong m \gg= (\text{fun } x \Rightarrow fx \gg= g)$$

$$\text{return } x \gg= f = fx = fx \gg= \text{return}$$
